

Task 3 – Rendering and State

Create a single-page React dashboard application. Be creative with your dashboard, for example: game characters, projects, courses, products, employees, quests, books, etc.

Your application must allow to:

- Add and remove items.
- Edit/change an item's status.
- Change a local state of an item.
- Filter items.
- Reorder or reverse the list.
- Reset an item's local state.
- Preserve the correct item's local state when filtering or reordering.
- Use `console.log()` to investigate component re-renders.

Requirements

- React functional components and `useState`.
- Multiple components with parent and child state.
- Props and conditional rendering.
- Render lists with `.map()` and stable keys.
- Each item should have several properties and its own local state
- Demonstrate state preservation and intentional state reset using keys.
- Must be a Single Page Application (SPA).
- CSS is required. The page should look clean, complete, and well-designed.
- Do not add unnecessary or unusable UI elements just to fill the page.
- Your dashboard should have its own theme/content;
- **Do not** use Redux, Context, external state libraries, or `useEffect`.

Submission

1. Attach (submission up to 1 point):
 - a. GitHub repository link
 - b. Deployed application link (via Github)
 - c. One screenshot of the application running in the browser
2. “Press Turn In” button before the deadline
3. Defence (up to 1 point). You should be able to explain re-rendering, reconciliation, component identity, keys, and state preservation/reset using your own application during the defense.
